(54) Title: GRAFFITI AND/OR ENVIRONMENTAL PROTECTIVE ARTICLE HAVING REMOVABLE SHEETS, SUBSTRATES
PROTECTED THEREWITH, AND A METHOD OF USE

(57) Abstract

This invention relates to an article comprising a transparent stack of sheets that may be applied, for example, to protect substrates such as glass or plastic windows, signage or displays. A topmost sheet can be peeled away after it is damaged to reveal an undamaged sheet below. The invention also relates to the protected substrates and a method of protecting substrates such as glass or plastic windows, signage and displays from vandalism or other surface damage by adhering the stack of sheets to the substrate to be protected and subsequently pulling a topmost sheet away from the stack after it becomes damaged.

5

Field of the Invention

This invention relates to an article comprising a transparent stack of sheets that may be applied, for example, to protect substrates such as glass or plastic windows, signage or displays. A topmost sheet can be peeled away after it is damaged to reveal an undamaged sheet below. The invention also relates to a method of protecting substrates such as glass or plastic windows, signage and displays from vandalism or other surface damage by adhering the stack of sheets to the substrate to be protected and subsequently pulling a topmost sheet away from the stack after it becomes damaged.

15

Background of the Invention

Windows and glass in public transportation vehicles such as buses or subway trains can be subjected to a tremendous amount of abuse. The windows can be damaged by both incidental scratching during cleaning or they can be maliciously damaged by vandalism. Vandals damage the windows by scratching or abrading the surface of the window with items such as lava rock, diamonds, abrasive papers or abrasive cloths. Vandals can also damage the window by painting or coloring the surface of the window. Cleaning processes have been defined to eliminate damage by painting or coloring. However, scratching of glass by vandals presents a significant problem. In one major city, for example, approximately 40 percent of the bus windows have been vandalized by scratching and close to 80 percent of the subway train windows. The public transportation officials now call this type of graffiti "scratchiti". The best approach to stopping graffiti historically has been to remove the graffiti immediately once it appears. This graffiti prevention system which is known as "zero tolerance", has been extremely successful in eliminating the written and painted vandalism. Scratched glass, however, is extremely difficult and expensive to repair and as a result, the zero tolerance approach to scratchiti prevention and elimination is cost prohibitive. The vandalism issue tarnishes the overall image of an

20
25
30

entire city's transportation system. The vandalized glass leads to lower ridership because of the reduced perception of safety on the vehicle by the public. The vandalism ultimately leads to lost revenue for the public transportation system and substantially high repair costs.

5 Several approaches have been evaluated to combat the scrachiti problem. The first approach has been to repair the glass by a multi-step abrasion/polishing method to remove the scrachiti. The abrasion steps remove glass to the depth of the scratch with diamond abrasives and then with subsequently finer grades of diamond or aluminum oxide abrasives the surface of the glass is polished to its original appearance. The abrasive
10 materials are expensive and the time required to completely abrade and polish the surface of the glass can be several hours depending on the depth of the damaged areas.

A second approach to eliminating the problem has been to apply a single permanent adhesive coated polyester sheet onto the surface of the window. The polyester sheet is thick enough to protect the window from scratching by diamonds, lava rocks and
15 most abrasives. The sheet is typically applied onto the glass with a water solution to eliminate any trapped air. The application process takes about 5 to 10 minutes to complete. The sheet does a good job of protecting the window from most of the damage but the sheet is readily damaged and the damage is visible to the passengers. Removing the sheet is very time consuming taking about 15 to about 60 minutes depending on the amount of residue
20 left on the window after removal of the sheet. Once the damaged sheet is removed, a new permanent adhesive coated polyester sheet needs to be applied. The time required to remove the adhesive coated polyester sheet, remove the adhesive residue from the glass, and apply a new permanent adhesive coated polyester sheet and reinstall the window can be close to 2 hours. Examples of single permanent adhesive coated polyester sheets which
25 can be used to protect a window are 3MTM ScotchshieldTM Safety and Security Window Film and 3MTM Sun Control Window Films, data sheet number 70-0703-7220-0 published in September 1996 by the 3M Company.

The replaced sheet can be quickly damaged once the vehicle is used again in public thus necessitating another costly and time consuming replacement.

30 The third approach commonly used to repair and protect windows from scratches is to coat the damaged window with an epoxy coating. (Enhancement of Vehicle Glazing for Vandal Resistance and Durability, by Daniel R. Bowman, March 25, 1996, available

from the United States Transportation Research Board). The damaged window is typically first scrubbed clean before coating with an epoxy coating. The epoxy coating can be used to fill the defects on the windows and restore the window to a state of clarity where signs can be read through the window. To apply the coating, the window must be removed from the vehicle and the window must be cleaned and primed. The coatings are applied and cured in a clean environment. The coatings currently available however are easily scratched by the same method used to scratch the glass. Once the coating is damaged, it is difficult to apply a subsequent coating due to poor adhesion of the coating to the first layer. The process to replace the damaged coating with a new coating is time consuming and expensive.

Another approach to the problem is to apply a sacrificial window as a shield over an original non-damaged window. The vehicle's window is modified with a frame that has a channel designed for a sheet of polycarbonate or acrylic. The rigid self-supporting sheet is inserted into the channel and acts as a barrier to damage on the base window. The polycarbonate sheet can be easily scratched by intentional methods being used to scratch the glass. This approach requires extensive modification to the window frame. Furthermore, the material cost per repair can be excessive making this approach cost prohibitive.

U.S. Patent No. 3,785,102 discloses a pad comprising a plurality of very thin polyethylene or polypropylene removable sheets, each sheet bearing a very thin coating of pressure sensitive adhesive on its top surface for removing dirt from shoes and an adhesive at the bottom surface so that each successive layer is removably adhered to successive bottom layers and eventually to the floor. There is no discussion regarding the clarity of such a pad.

3M Masking and Packaging Systems Division sells a stack of sheets with adhesive that removes lint and pet hair under the trade names Pat It™ Lint and Pet Hair Remover, product data sheet numbers 70-0705-7091-9, 70-0705-0819-0 and 70-0705-7038-0 published by 3M Company in 1994.

Research Disclosure 24109 (May 1984) discloses transmissive strippable plastic sheets stacked on mirror surfaces or stacked reflective (mirror surfaced) strippable plastic sheets that can be removed successively as toner or dust build up on the mirrors used in the optical imaging systems of electrophotographic reproduction apparatus occurs. The

adhesive joining the layers to one another are provided only about the border areas of the sheets which are outside the optical image path to minimize image quality losses.

JP 10167765A describes a method of cleaning windows by the application of an optically clear sheet of plastic film on the inner and outer surface of the glass. The film is comprised of polyvinyl chloride, polyacrylic acid, polyester or polycarbonate. The plastic film is thin and only a single sheet of plastic is described on each side of the glass. The sheet is removed when the sheet becomes soiled.

U.S. Patent No. 5,592,698 discloses a tear away lens stack for maintaining visibility through a transparent protective eye and face shield of a racing vehicle drivers helmet which includes a tab portion having projections formed thereon to assist in grasping the tab portion for rapid tear away. No adhesive is used in the stack; rather the lenses are clipped together.

A need thus exists for an article and a method for protecting windows, displays, and signage which is time and labor saving as well as cost effective.

Summary of the Invention

We have discovered such an article and a method. The present invention provides an article comprising a stack of sheets wherein the sheets are designed to be removable from each other such that a fresh sheet can be exposed after a topmost sheet above is damaged and then removed. The stack can be applied, for example, to the interior of bus or train windows to provide protection for the windows. As a sheet is damaged by graffiti artists, the topmost sheet of the article can be removed by trained maintenance personnel to reveal a clean undamaged sheet below. Preferably the time for each sheet removal is very fast (less than about 5 minutes, more preferably less than about 3 minutes and most preferably less than about 1 minute.) In addition, the articles of the invention are preferably cost effective. Using a preferred embodiment of the invention the speed of damage removal and low cost of damage removal allows the public transportation authorities to practice the "zero tolerance" scratchiti prevention system on the windows of public transportation vehicles.

The article of the invention can optionally be applied to backlit signage or highway/street signage that is in areas that make it susceptible to damage by graffiti artists,

weathering, or normal wear and tear. It can, for example, preferably be used on top of the typical plastic layer protecting a sign or in place of it.

The present invention provides an article comprising:

5 a stack of sheets, wherein each sheet independently comprises:

(a) a film, the film having a first side having a surface area and an opposite second side having a surface area;

(b) a bonding layer having a first side having a surface area and an opposite second side having a surface area, wherein the bonding layer is bonded via its first side to the
10 second side of the film such that at least a center of the surface area of the second side of the film is in contact with the bonding layer, wherein at least about 50 percent of the surface area of the second side of the film has the bonding layer bonded thereto;

(c) an optional release layer coated on the first side of the film;

wherein each sheet is stacked upon another sheet such that except for a
15 bottom sheet of the stack of sheets, the bonding layer of a sheet is in contact with the protective film or release layer, if present, of a sheet below;

wherein a topmost sheet can be removed from the stack of sheets by pulling it away from the stack such that the sheet being removed from the stack as well as the sheets remaining with the stack do not delaminate;

20 wherein the stack of sheets when subjected to a visual acuity test using a 3 meter Snellen eye chart can allow an observer with 6 meter/6 meter vision to read a line on the eye chart which is indicative of about 6 meter/12 meter vision or better.

In a preferred embodiment of the article of the invention the article when subjected
25 to a visual acuity test using a 3 meter Snellen eye chart can allow an observer with 6 meter/6 meter vision to read the line on the eye chart which is indicative of about 6 meter/6 meter vision or better.

In a preferred embodiment the first side of the film is not bonded to a bonding
30 layer of the same sheet. In other words, preferably each sheet has a bonding layer coated on the second side of the film only.

In a preferred embodiment of the article of the invention the bonding layer is continuous.

5 In a preferred embodiment, the article of the invention when subjected to a 180° Peel Adhesion to Glass test leaves substantially no residue (more preferably no residue) on the glass.

10 In a preferred embodiment of the article of the invention the stack of sheets is transparent.

In a preferred embodiment of the article of the invention each sheet has a penetration resistance of at least about 0.5 kg, even more preferably at least about 1 kg, even more preferably at least about 2 kg, even more preferably at least about 2.5, even more preferably at least about 3 kg, even more preferably at least about 3.5 kg, and most preferably about 4 kg.

15 With respect to the article of the invention preferably the maximum haze value of the stack of sheets is less than about 10 percent, more preferably less than about 5 percent, and most preferably less than about 3 percent.

20 In a preferred embodiment of the article of the invention at least about 80 percent (more preferably at least about 90 percent, and most preferably about 100 percent) of the surface area of the second side of the film has the bonding layer bonded thereto.

25 In a preferred embodiment of the article of the invention the bonding layer is continuous and any areas of the second side of the film not bonded to the bonding layer are margin(s).

30 Preferably the article of the invention comprises at least about 3 sheets, more preferably about 5 to about 10 sheets.

In a preferred embodiment of the article of the invention the release layer is present and the release layer of each sheet has a Taber abrasion resistance of about 25 percent or less, more preferably about 10 or less, and most preferably about 2 or less according to ASTM D1044-76 after 100 cycles.

5

In a preferred embodiment of the article of the invention the bonding layer comprises a material selected from the group consisting of acrylics, rubbers, polyolefins, and mixtures thereof.

10

In a preferred embodiment of the article of the invention the bonding layer comprises a pressure sensitive adhesive.

15

In a preferred embodiment of the article of the invention the bonding layer has a thickness ranging from about 5 to about 150 microns, more preferably about 10 to about 25 microns.

20

In a preferred embodiment of the article of the invention the film has a thickness ranging from about 25 to about 4000 microns, more preferably about 50 to about 1000 microns.

25

In a preferred embodiment of the article of the invention the film comprises a material selected from the group consisting of polyester, polycarbonate, acrylic, polyurethanes, poly acetyl, polyolefin based ionomers, ethylene vinyl acetate polymers, polyethylene, polypropylene, polyvinyl chloride, polystyrene, urethane acrylate polymers, epoxy polymers, epoxy acrylate polymers, and blends thereof.

30

In a preferred embodiment of the article of the invention the film further comprises of an additive selected from the group consisting of ultraviolet lights absorbers, ultraviolet light stabilizers, flame retardants, smoke suppressants, antioxidants, and mixtures thereof.

In a preferred embodiment of the article of the invention the film comprises multiple layers.

In a preferred embodiment of the article of the invention each sheet has a tensile strength of about 20 to about 2000 kP, an elongation of about 5 to about 1000% and a tear strength of about 0.05 to about 5 kg. Even more preferably each sheet has a tensile strength of about 70 to about 1400 kP, an elongation of about 5 to about 500% and a tear strength of about 0.5 to about 2.5 kg. Most preferably each sheet has a tensile strength of about 350 to about 1000 kP, an elongation of about 20 to about 100% and a tear strength of about 1.5 to about 2.5 kg.

10 In a preferred embodiment of the article of the invention the release layer is present.

In a preferred embodiment of the article of the invention the release layer has a thickness ranging from about 0.1 to about 25 microns, more preferably about 2.5 to about 5 microns.

20 In a preferred embodiment of the article of the invention the release layer comprises a material selected from the group consisting of acrylates, methacrylates, urethanes, silicones, polyolefins, fluorocarbons and mixtures thereof.

25 In a preferred embodiment of the article of the invention the bonding layer of each sheet further comprises a component selected from the group consisting of flame retardants, smoke suppressants, antioxidants ultraviolet light absorbers, ultraviolet light stabilizers, and mixtures thereof.

30 In a preferred embodiment of the article of the invention the topmost sheet is capable of being removed by gripping the sheet with an adhesive wand and pulling the sheet away from the stack of sheets of sheets.

In a preferred embodiment of the article of the invention the article further comprises a plurality of tabs, wherein a separate tab is bonded to a portion of the second

side of the bonding layer of each of the sheets in a manner such that the tab on the topmost sheet can be used to pull the topmost sheet away from the stack of sheets.

In a preferred embodiment of the article of the invention for each sheet at least a portion of a margin of the film does not have bonding material bonded thereto in a similar location such that the topmost sheet can be removed by grasping the portion of the barrier film without bonding material bonded thereto and pulling it away from the stack. Most preferably for each sheet the portion of the margin which does not have bonding material bonded thereto is a corner of the sheet.

In a preferred embodiment of the article of the invention for each sheet at least a portion of a margin of the bonding material is detackified in a similar location wherein the topmost sheet can be removed by grasping the sheet where the bonding material is detackified and pulling it away from the stack. Most preferably for each sheet the portion of the margin where the bonding material is detackified is a corner of the sheet.

In a preferred embodiment of the article of the invention each sheet has a hole which extends through that sheet in a margin of the sheet, wherein the holes in the sheets are staggered such that the holes do not overlap and wherein the topmost sheet can be removed from the stack of sheets by using a tool which can be inserted in the hole of the topmost sheet and used to pull the topmost sheet away from the stack.

The present invention also provides a construction comprising:

(i) an article comprising:

a stack of sheets, wherein each sheet independently comprises:

(a) a film, the film having a first side having a surface area and an opposite second side having a surface area;

(b) a bonding layer having a first side having a surface area and an opposite second side having a surface area, wherein the bonding layer is bonded via its first side to the second side of the film such that at least a center of the surface area of the second side of the film is in contact with the bonding layer, wherein at least about 50 percent of the surface area of the second side of the film has the bonding layer bonded thereto, wherein

with respect to each sheet the first side of the film is not bonded to a bonding layer of the same sheet;

(c) an optional release layer coated on the first side of the film;

5 wherein each sheet is stacked upon another sheet such that except for a bottom sheet of the stack of sheets, the bonding layer of a sheet is in contact with the protective film or release layer, if present, of a sheet below;

wherein a topmost sheet can be removed from the stack of sheets by pulling it away from the stack such that the sheet being removed from the stack as well as the sheets remaining with the stack do not delaminate;

10 wherein the stack of sheets when subjected to a visual acuity test using a 3 meter Snellen eye chart can allow an observer with 6 meter/6 meter vision to read a line on the eye chart which is indicative of about 6 meter/12 meter vision or better; and

(ii) a substrate to which the article is bonded via the bonding layer of the bottom
15 sheet.

In a preferred embodiment of the article of the invention the substrate comprises a material selected from the group consisting of glass, metal, plastic, painted surfaces, wood, fabric, wallpaper, ceramic, concrete, mirrored surfaces, plastic/glass laminates, and
20 combinations thereof.

In a preferred embodiment of the article of the invention the substrate is part of a structure. Most preferably the structure is selected from the group consisting of windows, walls, partitions, signs, bill boards, artwork, buildings, elevators, vehicles, furniture, and
25 doors.

In a preferred embodiment the structure comprises a window;
wherein the article is bonded via the bonding layer of the bottom sheet to the window, wherein the article has at least one edge;
30 and wherein the construction further comprises a frame which is attached to a least a portion of the window such that it extends over at least one edge of the article.
Preferably the frame extends over all the edge(s) of the article.

In another preferred embodiment the structure comprises a window;

wherein the article further comprises a plurality of tabs, wherein a separate tab is bonded to a portion of the second side of the bonding layer of each of the sheets in a manner such that the tab on the topmost sheet can be used to pull the topmost sheet away from the stack of sheets;

wherein the article is bonded via the bonding layer of the bottom sheet to the window, wherein the article has at least one edge;

and wherein the structure further comprises a frame which is attached to at least a portion of the window such that it extends over at least one edge of the article in a manner which covers the tabs.

In another preferred embodiment of the construction the structure is a window;

wherein for each sheet at least a portion of a margin of the film does not have bonding material bonded thereto in a similar location such that the topmost sheet can be removed by grasping the portion of the barrier film without bonding material bonded thereto and pulling it away from the stack;

wherein the article is bonded via the bonding layer of the bottom sheet to the window, wherein the article has at least one edge;

and wherein the construction further comprises a frame which is attached to at least a portion of the window such that it extends over at least one edge of the article in a manner such that it extends over the portion of the film margin that does not have bonding material bonded thereto.

In another preferred embodiment of the construction structure comprises a window;

wherein for each sheet of the article at least a portion of a margin of the bonding material is detackified in a similar location wherein the topmost sheet can be removed by grasping the sheet where the bonding material is detackified and pulling it away from the stack;

wherein the article is bonded via the bonding layer of the bottom sheet to the window, wherein the article has at least one edge; and wherein the construction further

comprises a frame which is attached to at least a portion of the window such that it extends over at least one edge of the article such that it extends at least over the portion of the sheet margin wherein the bonding material is detackified.

5 In another preferred embodiment of the construction the structure comprises a window;

wherein each sheet of the article has a hole which extends through that sheet in a margin of the sheet, wherein the holes in the sheets are staggered such that the holes do not overlap and wherein the topmost sheet can be removed from the stack of sheets by
10 using a tool which can be inserted in the hole of the topmost sheet and used to pull the topmost sheet away from the stack;

wherein the article is bonded via the bonding layer of the bottom sheet to the window, wherein the article has at least one edge; and wherein the construction further comprises

15 a frame which is attached to at least a portion of the window such that it extends over at least one edge of the article such that it extends at least over the holes in the sheets.

In another preferred embodiment of the construction

the structure comprises a vehicle comprising a window;

20 and wherein the article is bonded via the bonding layer of the bottom sheet to the window. Most preferably the vehicle is selected from the group consisting of buses, trains, and subways.

The present invention also provides a method comprising the steps of:

25 (a) applying an article comprising:

a stack of sheets, wherein each sheet independently comprises:

(i) a film, the film having a first side having a surface area and an opposite second side having a surface area;

30 (ii) a bonding layer having a first side having a surface area and an opposite second side having a surface area, wherein the bonding layer is bonded via its first side to the second side of the film such that at least a center of the surface area of the second side of the film is in contact with the bonding layer, wherein at least about 50 percent of the

surface area of the second side of the film has the bonding layer bonded thereto, wherein with respect to each sheet the first side of the film is not bonded to a bonding layer of the same sheet;

(iii) an optional release layer coated on the first side of the film;

5 wherein each sheet is stacked upon another sheet such that except for a bottom sheet of the stack of sheets, the bonding layer of a sheet is in contact with the protective film or release layer, if present, of a sheet below;

10 wherein a topmost sheet can be removed from the stack of sheets by pulling it away from the stack such that the sheet being removed from the stack as well as the sheets remaining with the stack do not delaminate;

wherein the stack of sheets when subjected to a visual acuity test using a 3 meter Snellen eye chart can allow an observer with 6 meter/6 meter vision to read a line on the eye chart which is indicative of about 6 meter/12 meter vision or better;

to a substrate via the bonding layer of the bottom sheet of the article;

15 (b) allowing the topmost sheet of the article to be damaged;

(c) removing the damaged topmost sheet of the article by gripping the sheet and pulling it away from the stack, in a manner such that neither the sheet being removed nor the stack of sheets which remains delaminates, in order to expose a lower sheet of the article which thence becomes the topmost sheet of the article.

20

In a preferred embodiment of the method, steps (b) and (c) are repeated at least once. More preferably steps (b) and (c) are repeated until the bottom sheet is removed, and the bottom sheet upon removal leaves substantially no adhesive residue (most preferably) on the substrate.

25

Brief Description of the Drawings

In a preferred embodiment of the article of the invention the sheets are rectangular sheets of the same length and width.

Fig. 1 is a cross-sectional view taken along line 1-1 of the construction of Fig. 5.

30 Fig. 2 is a cross-sectional view taken along line 2-2 of the construction of Fig. 6.

Fig. 3 is a cross-sectional view taken along line 3-3 of the construction of Fig. 7 showing a person peeling away a damaged topmost sheet to reveal a new topmost sheet.

Fig. 4 is a cross-sectional view of the construction of Fig. 8 taken along line 4-4 showing a stack of four sheets which is undamaged. Fig. 4 is identical to Fig. 3 except that damaged topmost sheet has been removed.

Detailed Description of the InventionArticle

With respect to the article of the invention, preferably the stack of sheets has no effect on visual acuity. The test for the effect on visual acuity appears later herein. This test can be used to determine the effect of an observer to discern images when looking through the article of the invention.

Preferably the article (as well as the stack of sheets and each individual sheet) has a haze value of less than about 10 percent, more preferably less than about 5 percent, and most preferably less than about 3 percent.

The article of the invention as well as the sheets making up the article are typically colorless although they may optionally be tinted. The sheets may optionally have a graphic thereon which would typically be on the edge of each sheet.

Sheets

Preferably the article comprises at least about 3 sheets, typically about 5 to about 10 sheets. Preferably each sheet has the same length, width, and shape. In a preferred embodiment each sheet is rectangular in shape.

Each sheet preferably provides a protective barrier to preferably prevent damage to a substrate to be protected such as a glass window as well as any sheets below the exposed topmost sheet. The sheet preferably resists penetration and damage from conventional scratching tools such as razor blades, knives, lava rocks, abrasive cloths, diamonds and carbide tipped styli. Preferably at least one (more preferably each) sheet has a penetration resistance of at least about 0.5 kg, more preferably at least about 2 kg, and most preferably at least about 4 kg.

Effect on visual acuity and color preferably remain stable upon exposure to a variety of environmental conditions.

The sheet is preferably easily removable, preferably in a continuous piece. The following tests which evaluate the integrity and removability of a sheet can be used to help predict the removability of a sheet.

Preferably at least one sheet (more preferably each sheet as well as each film making up the sheet) has a tensile strength when subjected to ASTM D882 of about 20 to about 2000 kP, more preferably about 70 to about 1400 kP, and most preferably about 350 to about 1000 kP. Preferably at least one sheet (more preferably each sheet as well as each

film making up each) has an elongation when subjected to ASTM D882 of about 5 to about 1000%, preferably about 5 to about 500 percent, and most preferably about 20 to about 100 percent.

5 Preferably at least one sheet (preferably each sheet as well as each film making up each sheet) has a tear strength when subjected to ASTM D1004 of about 0.05 to about 5 kg, more preferably about 0.5 to about 2.5 kg, and most preferably about 1.5 to about 2.5 kg.

Film

10 Preferably the film comprises a material selected from the group consisting of polyester, polycarbonate, acrylic, polyurethanes, poly acetyl, polyolefin based ionomers, ethylene vinyl acetate polymers, polyethylene, polypropylene, polyvinyl chloride, polystyrene, urethane acrylate polymers, epoxy polymers, epoxy acrylate polymers, and blends thereof. In one embodiment the film comprises multiple layers.

15 The thickness of the film depends on the type of damage that the film may be subjected to and the composition of the film. Typically the film has a thickness of about 25 to about 4000 microns for reasons of weight, visual acuity and economics, preferably about 50 to about 1000 microns and most preferably about 50 to about 250 microns.

20 The film can optionally further comprise stabilizers and fillers which enhance the durability of the film upon exposure to ultraviolet light and/or heat. Additives can also be incorporated into the film that reduce the flammability of the film or smoke generation during combustion.

Bonding Layer

25 The bonding layer preferably provides a stable bond between the film layers. It is intended to prevent premature separation of the sheets under the environmental conditions anticipated in the application. It preferably serves to act as an optically clear interface between the films. However, it must bond more readily to the film of the same sheet than to the film of the sheet below.

30 In a preferred embodiment the first side of the film is not bonded to a bonding layer. The bonding layer as well as the other layers making up a sheet preferably do not change color when subjected to environmental conditions. Furthermore, the stability of

the bonding layer preferably should not change dramatically on exposure to a wide range of conditions.

5 The bonding layer may comprise a pressure sensitive adhesive system or a non-pressure sensitive adhesive system. Preferably the bonding layer comprises a pressure sensitive adhesive. The bonding layer preferably comprises a material selected from the group consisting of acrylics, for example, which are thermally cured, ultraviolet light
10 cured, electron beam cured and can be solvent based, waterbased or 100 percent solids; rubbers, for example, which can be thermoplastic rubbers, block copolymers, natural rubbers or silicone rubbers; and polyolefins which can, for example, be ethylene vinyl acetate polymers, poly-alpha olefins (C₃-C₁₀) copolymers or blends of poly-alpha olefins with ethylene or propylene based polymers; and mixtures thereof.

The bonding layer may optionally further comprise a component selected from the group consisting of tackifiers, oils, stabilizers, flame retardants fillers, and mixtures thereof subject to obtain the desired properties. Preferably the bonding layer further
15 comprises a component selected from the group consisting of ultraviolet light absorbers, ultraviolet light stabilizers and mixtures thereof. Preferably the component selected from the group consisting of ultraviolet light absorbers, ultraviolet light stabilizers and mixtures thereof is used in an amount to inhibit degradation of the article from ultraviolet radiation, preferably about 0.5 to about 1 percent by weight based on the total weight of the bonding
20 layer.

Preferably at least about 80 percent, more preferably at least about 90 percent, and most preferably about 100 percent of the surface area of the second side of the film has the bonding layer bonded thereto. Preferably the bonding layer is continuous. Preferably any areas of the film not covered by the bonding layer are margin(s).

25 Preferably the bonding layer has a thickness ranging from about 5 to about 150 microns, more preferably about 10 to about 50 microns, and most preferably about 10 to about 25 microns.

Optional Release Layer

30 The optional release layer preferably prevents light scratching of the surface of the film and in addition can provide a release surface for the bonding layer on the sheet above. This optional release layer is preferably bonded to the film layer in a manner so as to

maintain the bond after a variety of environmental exposures. In addition, the release layer preferably remains clear after environmental exposures. It preferably maintains scratch resistant over time. It preferably forms a stable adhesion to the bonding layer and provides a consistent surface for removal of the sheet above.

5 Preferably the release layer, if present has a thickness ranging from about 0.1 to about 25 microns, more preferably about 2.5 to about 5 microns.

 Preferably the release layer comprises a material selected from the group consisting of acrylates, methacrylates, urethanes, polyolefins, silicones, fluorochemicals such as fluorocarbons, and mixtures thereof.

10 U.S. Patent No. 5,633,049 describes a method of making a protective coating for thermoplastic transparencies particularly aircraft transparencies. The coating is prepared from a silica-free protective coating precursor composition comprising a multifunctional ethylenically unsaturated ester of acrylic acid, a multifunctional ethylenically unsaturated ester of methacrylic acid, or a combination thereof; and an acrylamide. Such a protective
15 coating may be useful as a release coating for the article of the present invention.

 The release layer may optionally further comprise a filler such as ceramer particles, for example, as described in U.S. Patent No. 5,104,929, in order to provide enhanced abrasion resistance properties.

 The adhesion of the bonding layer to the release layer can be adjusted, for
20 example, by incorporation of flow additives such as silicones, acrylics or fluorochemicals to the release layer.

 The release layer can optionally be selected to improve the Taber Abrasion Resistance of the sheet. Release materials which may provide good Taber Abrasion Resistance properties include but are not limited to multifunctional acrylates or
25 methacrylates.

 The release layer on the top surface of the film layer may provide uniform release performance across the sheet. Optionally, a differential release layer can be coated on the film surface. Such a differential release layer can be used to make the initial separation of a sheet from the stack of sheets easier. Differential release can be obtained, for example,
30 by coating a material providing easy release at the edge and/or corner of the sheet and coating a material providing tighter release on the balance of the sheet surface.

Suitable multifunctional ethylenically unsaturated esters of (meth)acrylic acid are the polyacrylic acid or polymethacrylic acid esters of polyhydric alcohols including, for example, the diacrylic acid and dimethylacrylic acid ester of aliphatic diols such as ethyleneglycol, triethyleneglycol, 2,2-dimethyl-3,3-propanediol, 1,3-cyclopentanediol, 1-ethoxy-2,3-propanediol, 2-methyl-2,4-pentanediol, 1,4-cyclohexanediol, 1,6-hexamethylenediol, 1,2-cyclohexanediol, 1,6-cyclohexanedimethanol; the triacrylic acid and trimethacrylic acid esters of aliphatic triols such as glycerin, 1,2,3-propanetriol, 1,2,4-butanetriol, 1,2,5-pentanetriol, 1,3,6-hexanetriol, and 1,5,10-decanetriol; the triacrylic acid and trimethacrylic acid esters of tris(hydroxyethyl) isocyanurate; the tetraacrylic and tetramethacrylic acid esters of aliphatic triols, such as 1,2,3,4-butanetetrol, 1,1,2,2-tetramethylolethane, 1,1,3,3-tetramethylolpropane, and pentaerythritol tetraacrylate; the pentaacrylic acid and pentamethacrylic acid esters of aliphatic pentols such as adonitol; the hexaacrylic acid and hexamethacrylic acid esters of hexols.

Preferably the release layer is present and the release layer of at least one sheet (preferably each sheet) has a Taber abrasion resistance of about 25 or less (more preferably about 10 or less and most preferably about 2 or less) as measured according to ASTM D1044-76 after 100 cycles. The release layer is not required if the bonding layer is anchored well to the film. For example, the film surface coated with the bonding layer may be chemically primed or oxidized with a corona discharge treatment or flame treatment. The film surface not coated with the bonding layer would be free of surface treatments. This adhesion differential between the two sides of the film facilitates clean separation of sheets from the stack. The film may also be soluble in the solvents or monomers used for the bonding layer. By coating a bonding layer on a soluble film and curing or evaporating, the bonding layer can become entangled with the film. The adhesion of the bonding layer to the coated film surface is greater than adhesion to the laminated surface in the stack of sheets. due to the differential in adhesion, clean separation of a sheet from a stack can be obtained.

Optional Prime Layer

An optional prime layer can be used to provide an adhesion promoting interface between the bonding layer and the film of the same sheet. Alternatively the film surface

can optionally be modified via corona discharge treatments in a variety of atmospheres or by using a flame in order to promote adhesion between the bonding layer and the film of the same sheet. A prime layer can be, for example, an aziridine based prime layer or a grafted surface such as an acrylamide/multifunctional acrylate polymerized into the film surface with high-energy radiation. Other examples of prime layers include, for example, acrylics, polyvinylidene chloride and solution coated polyesters.

A prime layer can be, for example, a high tack pressure sensitive adhesive with a composition similar to the bonding layer. It can also, for example, be a coextruded interface prepared as a component of the film or resin solution coated on the film.

Preparation of the Article of the Invention

The article of the invention can be made in a number of different ways. One method of making the article of the invention is to apply the optional release coating on the surface of a film. The release coating could be applied by roll coating, gravure coating, or by an air knife coating process, for example. Any solvent(s) present in the coating are evaporated in an oven. The release coating can then be cured with ultraviolet (UV) light or with an electron beam. Alternatively, the opposite surface of the film may optionally be primed either with a surface treatment such as corona treatment or a flame treatment. The prime could also be a chemical prime. The chemical prime could be pre-applied by the film supplier or applied, for example, by roll coating, gravure coating, or by an air knife coating process. The solvent(s) are evaporated from the priming layer. The prime layer may be coated with the bonding layer by a variety of methods including notch bar coating, curtain coating, or slot die coating of a solution or latex. Another method of applying the bonding layer is extrusion coating of a 100% solids bonding layer. Depending on the chemistry of the coating, the bonding layer material is dried and/or cured to form a finished polymer. When the bonding layer is tacky at room temperature the bonding layer is preferably protected by a smooth release film. A stack of sheets can be prepared by removing the release liner from the bonding layer and laminating the bonding layer to the release surface of an adjacent sheet. The end application dictates the number of sheets in the stack. The stack of sheets can be cut into a desired shape by die cutting with a steel rule die, laser or with a water jet.

Another approach to forming a stack of sheets is to prepare a film with a primed surface and an opposite release surface. An ultraviolet curable liquid bonding layer is applied to the primed surface of one film and laminated in the liquid state to the release surface of a subsequent film. The liquid is cured. An ultraviolet curable liquid bonding layer is applied to the primed surface of a third film and laminated to the exposed release surface of the first laminated sheets. The liquid is cured resulting in a stack of three sheets. This lamination and curing process can be repeated until the desired number of sheets in a stack is obtained.

Other approaches to making the article of the invention are also possible.

Application of Article to Substrate

The article of the invention can be applied to a substrate in a number of different ways. For example, it can be applied by spraying an alcohol/water solution such as a 25% isopropanol/75% water solution on to the surface of the substrate. The release liner is removed from the bottom sheet of the stack of sheets to expose a bonding layer and the exposed bonding layer is also sprayed with the same isopropanol/water solution. The substrate and the saturated bonding layer are brought into contact and the excess solution is removed from the interface with a roller or a squeegee. The stack of sheets could also be applied to a substrate with a dilute solution of dishwashing detergent in water such as for example a 0.5% Joy™ dishwashing detergent 99.5% water solution. The stack of sheets could also be applied directly to the substrate with high pressure lamination without a liquid interface. The stack of sheets could be applied to the substrate by applying an ultraviolet light curable coating on the substrate as the liquid interface. The stack of sheets is applied, the excess air is removed by a roller or squeegee and the coating is cured.

Removal of Sheets

In one embodiment of the article of the invention the topmost sheet is capable of being removed by gripping the sheet with an adhesive wand and pulling the sheet away from the stack of sheets.

In another embodiment the article further comprises a plurality of tabs, wherein a separate tab is bonded to the second side of the bonding layer of each of the sheets in a

manner such that the tab on the topmost sheet can be used to pull the topmost sheet away from the stack of sheets.

5 In another embodiment of the article for each sheet at least a portion of a margin of the film does not have bonding material bonded thereto in a similar location such that the topmost sheet can be removed by grasping the portion of the barrier film without bonding material bonded thereto and pulling it away from the stack. Preferably for each sheet the portion of the margin which does not have bonding material bonded thereto is a corner of the sheet.

10 In another embodiment of the article for each sheet at least a portion of a margin of the bonding material is detackified in a similar location wherein the topmost sheet can be removed by grasping the sheet where the bonding material is detackified and pulling it away from the stack. Preferably for each sheet the portion of the margin where the bonding material is detackified is a corner of the sheet.

15 In another embodiment of the article each sheet has a hole which extends through that sheet in a margin of the sheet (preferably the same margin), wherein the holes in the sheets are staggered such that the holes do not overlap and wherein the topmost sheet can be removed from the stack of sheets by using a tool (such as a pick) which can be inserted in the hole of the topmost sheet and used to pull the topmost sheet away from the stack.

20 The article of the invention can be better understood by referring to the following Figures 1 to 13. Fig. 1 is a cross-sectional view taken along line 1-1 of the construction of Fig. 5. The article 2 of the invention is bonded via bonding layer 44 to a glass window pane 4. The article 2 comprises a stack of five sheets (6, 8, 10, 12, and 14) bonded together. Sheet 6, which is the topmost sheet in Fig. 1, comprises top release layer 16, inner film layer 18, and lower bonding layer 20. Sheet 8 comprises top release layer 22, inner film layer 24, and lower bonding layer 26. Sheet 10 comprises top release layer 28, inner film layer 30, and lower bonding layer 32. Sheet 12 comprises top release layer 34, inner film layer 36, and lower bonding layer 38. Sheet 14, which is the bottom sheet of article 2, comprises top release layer 40, inner film layer 42, and lower bonding layer 44.

25 Fig. 2 is a cross-sectional view of the construction of Fig. 6. Fig. 2 shows the topmost sheet 6 being scratched 48 by rock 46.

30 Fig. 3 is a cross-sectional view of the construction of Fig. 7 showing a person peeling away the damaged topmost sheet 6 to reveal a new topmost sheet 8. Since no

bonding material is present along a portion of a corner margin of each sheet a convenient place for grasping 21 and removing the sheet is provided.

Fig. 4 is a cross-sectional view of the construction of Fig. 8 showing a now four sheet stack of sheets which is undamaged, wherein the topmost sheet is now sheet 8. Fig. 8 is identical to Fig. 7 except that damaged topmost sheet 6 has been removed.

Fig. 5 is a plan view of a construction comprising article 2 of the invention on a window. An observer 53 can view a tree 50 through the undamaged window 4 and article 2. A rim 52 extends around the window 4.

Fig. 6 illustrates a plan view of the construction of Fig. 5 wherein the top sheet 6 of the article 2 is being damaged by a rock 46.

Fig. 7 illustrates a plan view of the construction of Fig. 6 wherein the damaged sheet 6 is being peeled away to reveal an undamaged sheet 8.

Fig. 8 illustrates how the observer 53 can now clearly view the tree 50 after the damaged sheet 6 of Fig. 7 has been removed and undamaged sheet 8 has been revealed.

Fig. 9 is a plan view of a construction comprising the article of the invention 60 bonded via bonding layer 94 (not shown) to a glass window pane 62 (not shown) of a window. A window comprises a window pane and the framework in which the window pane is situated. (Articles of the invention are typically bonded to the window pane, typically the entire window pane.) (Items not illustrated in Fig. 9 are illustrated in Fig. 11) which is a cross-sectional view of Fig. 9B taken along line 11-11. The article 60 comprises a stack of four sheets (64, 66, 68, and 70) bonded together. Sheet 64, which is the topmost sheet, comprises top release layer 72, inner film layer 74, and lower bonding layer 76. Sheet 66, comprises top release layer 78, inner film layer 80, and lower bonding layer 82. Sheet 68, comprises top release layer 84, inner film layer 86, and lower bonding layer 88. Sheet 70, which is the bottom layer of article 60, comprises top release layer 90, inner film layer 92, and lower bonding layer 94. Tabs 96, 98, 100 and 102 are positioned between the sheets 64, 66, 68 and 70 between such that they are bonded to the bonding layer of the sheet above the tab. Frame 52 which covers the tabs is attached to the framework of the window. An observer 53 can view a tree 50 through the undamaged window 62 and article 60. A rim 52 extends around the window.

Fig. 9A illustrates a plan view of the article construction of Fig. 9 wherein the topmost sheet 64 of the article is being damaged by a rock 46. Scratches 61 are shown.

Fig. 9B illustrates a plan view of the construction of Fig. 9B wherein the frame 52 has been removed to expose the tabs and wherein the topmost damaged sheet 64 is being peeled away to reveal an undamaged sheet 66.

Fig. 10 is a plan view of the construction comprising article 110 on window pane 112 (shown in Fig. 12). An observer 53 can view a tree 50 through the undamaged window and article. A rim 52 extends around the window. Frame 56 is attached to the window frame and extends over through holes 53, 55, 57, and 59 (not shown).

Fig. 10A illustrates a plan view of the construction of Fig. 10 wherein the topmost sheet of the article is being damaged by a rock 46. The scratches are identified as 47.

Fig. 10B illustrates a plan view of the construction of Fig. 10A wherein the frame 56 has been removed and the damaged topmost sheet 114 is about to be peeled away to reveal an undamaged sheet 66 (not shown).

Fig. 12 is a cross-sectional view taken along line 12-12 of Fig. 10B. The article of the invention 110 is bonded via bonding layer 144 to a glass window 112. The article 110 comprises a stack of four sheets (114, 116, 118, and 120) bonded together. Sheet 114, which is the topmost sheet, comprises top release layer 122, inner film layer 124, and lower bonding layer 126. Sheet 116, comprises top release layer 128, inner film layer 130, and lower bonding layer 132. Sheet 118, comprises top release layer 134, inner film layer 136, and lower bonding layer 138. Sheet 120, which is the bottom sheet, comprises top release layer 140, inner film layer 142, and lower bonding layer 144. Through holes 154, 156, 152, and 150 are created in the stack of sheets 114, 116, 118, and 120 after the stack is prepared. They are staggered along a margin of the article when viewed from above the topmost sheet.

Fig. 13 illustrates a cross-sectional view of a window pane 4 having an article 2 of the invention bonded to each side thereof. Preferably such an article would have the preferred visual acuity and haze values discussed elsewhere herein. Each article 2 comprises a topmost sheet 6 (the exposed sheet which is farthest from the substrate being protected), and sheets 8, 10, 12, and 14. Sheet 6 comprises top release layer 16, inner film layer 18, and lower bonding layer 20. Sheet 8 comprises top release layer 22, inner film layer 24, and lower bonding layer 26. Sheet 10 comprises top release layer 28, inner film layer 30, and lower bonding layer 32. Sheet 12 comprises top release layer 34, inner film

layer 36, and lower bonding layer 38. Sheet 14 comprises top release layer 40, inner film layer 42, and lower bonding layer 44.

Test Methods

5 Penetration Resistance

A white painted steel panel from Advanced Coating Technologies in Hillsdale Michigan is used as a base. A 50 mm x 150 mm test sample is secured to the painted surface of the steel panel using a 100 mm x 50 mm piece of No. 232 Scotch™ Masking Tape from 3M Company along the long edges of the sample such that a 125 mm x 50 mm
10 portion of the sample is in direct contact with the painted panel. (In the case of a sheet or stack of sheets the exposed adhesive layer is placed in contact with the painted panel.) The panel with the sample on the top surface is placed onto an electronic balance with a capacity of 20 kg. The balance is tared to the combined weight of the panel and sample. Using a stainless steel coated industrial single edge razor blade, apply a force of 0.5 kg to
15 the test sample and hold for 2 seconds. Remove the blade from the test sample and repeat identically the force application and removal at a site 0.5 cm away from the original test site. Repeat the force application and removal at a site 0.5 cm away from the second site and at least 0.5 cm away from the first site to thus obtain 3 replicates at this force level. Color each force application test area with a black Sharpie™ felt tipped permanent marker
20 from the Sanford Corp. The ink will flow through a penetrated area of the test sample and produce a mark on the white metal panel. Remove the test sample from the base panel and observe any marks on the base panel. If no marks are present the sample has passed the test. If any marks are present the sample has failed the test. Repeat the test using the following forces in the test: 1 kg, 1.5 kg, 2 kg, 2.5 kg, 3 kg, 3.5 kg, and 4 kg. The force
25 required to penetrate the sample is recorded.

Effect of Sample on Visual Acuity of Observer

An observer with 6 meter/6 meter vision is positioned 3 meters from a 3 Meter Snellen eye chart, covers one eye and read with the uncovered eye the line which
30 corresponds to 6 meter/6 meter vision. The observer will be considered to have 6 meter/6 meter vision if the observer has that vision unaided or has that vision with corrective lenses as long as the corrective lenses are worn during the testing. A 75 mm x 75 mm

sample of the article or material to be evaluated is then placed 3 centimeters in front of the observer's uncovered eye while the other eye remains covered to determine if the sample causes a loss of visual acuity. If the sample has a protective release liner, the release liner is removed prior to conducting the test. If the viewer can still read the line of letters
5 indicative of 6 meter/6 meter vision it is considered that there is no interference with visual acuity caused by the sample. If the line indicative of 6 meter/6 meter vision cannot still be read the smallest line which can still be read is recorded, (For example 6 meter/9 meter, 6 meter/12 meter, 6 meter/15 meter, 6 meter/18 meter, etc.).

10 Appearance After 120 hours at 23°C and 180 Degree Peel Adhesion Between a Bonding Layer of a Sheet and the Surface of an Adjacent Supported Film

A supported film is prepared as follows. A 105 mm x 305 mm piece of 467 VHBTM Transfer Adhesive from 3M Company is removed from a roll. The transfer adhesive is an acrylic adhesive coated on a paper liner where both surfaces of the paper
15 liner were treated with a differential silicone release such that the adhesive releases from one side of the liner easier than the other side. The sheet of transfer adhesive was laminated with a rubber roller to the entire surface of a 100 mm x 300 mm rectangular painted white metal panel from Advanced Coatings Technology of Hillsdale, Michigan. The release liner is removed from the transfer tape exposing the adhesive on the entire
20 surface of the metal panel. To the adhesive is applied a 110 mm x 320 mm film in such a way that film/adhesive/panel laminate is free of bubbles. The film is applied to the panel such that the release surface (the release layer or the surface of the first side of the film if there is no release layer present) is on the opposite surface of the film from the adhesive coated panel. Any excess film and adhesive was trimmed away.

25 To this panel supported film is laminated a 25 mm x 150 mm sample of the sheet to be tested. (The sheet to be tested typically comprises a film with a bonding layer coated on one surface thereof.) The sample sheet is bonded to the panel supported film via its bonding layer. A rubber roller is used and in such a way that 100 mm of the sheet is bonded onto the panel supported film and 50 mm of the sheet hangs freely over the edge
30 of the panel supported film. This assembly is allowed to dwell for 120 hours at room temperature and about 50 % relative humidity (R.H.).

The over-hanging edge of the sample sheet is clamped to a sensor of a Slip-Peel Tester Model SP-102C-3090 adhesion tester (IMASS Inc. Accord, MA). The rest of the assembly is firmly clamped onto a carriage of the Slip-Peel Tester. As the carriage moves upon operation of the tester the sheet sample is peeled from the panel supported film at a rate of 228.6 cm/min and at an angle of 180 degrees. The average force required to remove the sheet sample from the panel-supported film over a 2-second test period is recorded. The test was conducted at about 23°C and about 50% relative humidity.

Typical 180 degree peel adhesion values for a sheet of the article of the invention range from about 50 to about 2000 g/2.54 cm. The 180 degree peel adhesion values at the lower end of the range facilitate easy stripping of one sheet from another sheet. The 180 degree peel adhesion values at the upper end of the range make stripping of the sheets more challenging but the integrity of the stack (the ability of the stack to resist premature separation) can be maintained better when vandals scratch the surface of the stack. The preferred 180 degree peel adhesion range is about 500 to about 1500 g/ 2.54 cm. The most preferred 180 degree peel adhesion range is about 750 to about 1250 g/ 2.54 cm.

Appearance After Heat Aging and 180 Degree Peel Adhesion Between a Bonding Layer of a Sheet and the Surface of an Adjacent Supported Film

The 180 degree peel adhesion force between a bonding layer on a sheet sample and the surface of an adjacent supported film is evaluated as described in the test method entitled "180 Degree Peel Adhesion Between a Bonding Layer of a Sheet and the Surface of an Adjacent Supported Film" except the assembly is aged for 5 days at 80 ° C. The assembly is examined for discoloration, blistering, and adhesive residue. Preferably the test sample is not discolored or blistered. The test sample is allowed to equilibrate to room temperature for 2 hours prior to testing. The test was conducted at about 23°C and 50% relative humidity.

The 180 degree peel adhesion value of a sheet of the article of the invention should preferably be stable compared to the room temperature adhesion value measured according to the test entitled "Appearance After 120 hours at 23°C and 180 Degree Peel Adhesion Between a Bonding Layer of a Sheet and the Surface of an Adjacent Supported Film". The 180 degree peel adhesion after heat aging preferably should not increase more

than about 50 % and should not decrease more than about 25%. The test sample preferably leaves no residue such as adhesive residue upon removal.

5 Appearance After Continuous Exposure to Condensing Humidity and 180 Degree Peel Adhesion Between a Bonding Layer of a Sheet and the Surface of an Adjacent Supported Film

10 The adhesion force between a bonding layer of a sheet and the surface of an adjacent supported film is evaluated as described in the test method entitled "Appearance After 120 hours at 23°C and 180 Degree Peel Adhesion Between a Bonding Layer of a Sheet and the Surface of an Adjacent Supported Film" except that the assembly is first continuously aged in a chamber that is maintained at 38°C and 100% relative humidity for 5 days prior to appearance evaluation and 180 degree peel adhesion testing. The assembly is examined for discoloration and blistering. The assembly is allowed to equilibrate to room temperature for 2 hours prior to testing for 180 degree peel adhesion. The test was
15 conducted at about 23°C and 50% relative humidity.

20 The 180 degree peel adhesion value of a sheet of the article of the invention should preferably be stable compared to the room temperature 180 degree peel adhesion value as measured according to the test method entitled "Appearance After 120 hours at 23°C and 180 Degree Peel Adhesion Between a Bonding Layer of a Sheet and the Surface of an Adjacent Supported Film". The level of 180 degree peel adhesion after condensing humidity exposure preferably should not increase more than about 50 % or decrease more than about 25%. The test sample preferably leaves no residue such as adhesive residue upon removal.

25 Appearance After an Environmental Cycling Test and 180 Degree Peel Adhesion Between a Bonding Layer on a Sheet Sample and the Surface of a Supported Adjacent Film

30 The adhesion force between a bonding layer on a sheet sample and the surface of a supported adjacent film is evaluated as described in the test method entitled "Appearance After 120 hours at 23°C and 180 Degree Peel Adhesion Between a Bonding Layer of a Sheet and the Surface of an Adjacent Supported Film" except that prior to testing the assembly is first aged in a controlled environmental chamber that is programmed to conduct the following continuous cycle: 4 hours at 40 ° C/100% relative humidity (RH),

followed by 4 hours at 80 ° C and then followed by 16 hours at -40 ° C. The sample is exposed 10 times to this cycle. The sample is examined for discoloration and blistering. Preferably the aged sample does not experience discoloration or blistering. The sample is allowed to equilibrate to room temperature for 2 hours before 180 degree peel adhesion testing. The peel adhesion test was conducted at about 23°C and about 50% humidity.

The 180 degree peel adhesion value of a sheet of the article of the invention should preferably be stable compared to the room temperature adhesion value as evaluated in the test method entitled "Appearance After 120 hours at 23°C and 180 Degree Peel Adhesion Between a Bonding Layer of a Sheet and the Surface of an Adjacent Supported Film". The level of 180 degree peel adhesion of a sheet of the article of the invention after thermal cycling preferably should not increase more than about 50 % or decrease more than about 25%. The test sample preferably leaves no residue such as adhesive residue on removal.

180 Degree Peel Adhesion to Glass

A 100 mm x 200 mm flat glass plate is cleaned with toluene and allowed to air dry prior to application of a sheet sample to be tested. (The sheet to be tested typically comprises a film and a bonding layer bonded to one side thereof.) The adhesion to glass is measured by bonding a 25 mm x 150 mm of the sheet sample to be tested using a rubber roller such that no trapped air and 25 mm x 50 mm of the sheet is hanging over the edge of the glass. The sheet is applied such that the bonding layer of the sheet is in contact with the glass. The sheet is allowed to dwell on the glass at least 10 minutes but less than 60 minutes. The glass plate is clamped onto the carriage of a Slip-Peel Tester Model SP-102C-3090 adhesion tester (IMASS Inc., Accord MA). The overhang of the sheet is clamped to a sensor of the tester. As the carriage moves upon operation of the tester the force to peel the sheet is measured at 228.6 cm/min at an angle of 180 degrees. The average force over a 2 second period is recorded. The test is conducted at about 23°C and about 50% R.H.

Typically the 180 degree peel adhesion to glass of a sheet of an article of the invention is about 100g/2.54 cm to about 5000 g/2.54 cm, preferably about 500g/2.54 cm to about 3000 g/2.54 cm, and most preferably about 1500 g/2.54 cm to about 2500g/2.54 cm. One hundred eighty degree peel adhesion above about 5000 g/2.54 cm is less preferred, because the sheet may be difficult to remove after a prolonged time on the glass.

One hundred eighty degree peel adhesion below about 100 g/2.54 cm is less preferred, because the bond to the glass could potentially be disrupted when the individual sheets are removed from the stack.

The glass panel is inspected for residue left after the sheet sample is peeled from the glass. Preferably substantially no residue (such as adhesive residue) remains on the glass. Most preferably no visible residue (such as adhesive residue) remains on the glass. The percentage of the area of the test panel where the sample was initially applied on which any residue remained is recorded.

10 Haze Test

The haze of a sample is measured by using a Garner XL211 Hazeguard device. The procedure used is in accordance to ASTM D1003-95 with the following exceptions

1. The sample size is rectangular with a minimum size of 40 mm x 40 mm.
2. The sample is scanned for areas of the maximum haze. These selected areas are measured and the maximum haze value is reported.
3. The sample is allowed equilibrate at 23°C and 50% R.H. for 72 hours prior to testing.
4. If printed or embossed images or graphics are contained on the sample, those areas of the sample should be avoided when measuring the maximum haze of the sample.
5. Prior to conducting the haze test, the release liner (if any) is removed from the sample.

Scratch Resistance

A 1.2 kg hammer manufactured by Collins Axe Company is provided. A tungsten carbide tipped stylus from General Tools Manufacturing Co. Inc. New York, New York is taped securely to the very top of the metal head of the hammer such that the tip of the nail points in substantially the same downward direction as does the hitting end of the hammer head. The nail is positioned such that it is substantially perpendicular to the handle of the hammer. The stylus protrudes from the hammer 2.5 cm. The tape used is No 471 tape from 3M Company. The sheet sample is attached to a 100 mm x 300 mm white painted metal panel and held securely in place. The hammer is held at the end of the handle while the

carbide stylus bears the weight of the hammer. A straight edge is taped to the sheet sample as a guide. The hammer is pulled down the length of the panel at about 200 cm/min such that the weight of the hammer is on the stylus. The hammer is pushed back up the length of the panel. Each up and down motion consisted of one cycle. The number of cycles
5 needed to scratch through the sample and into the white paint is reported.

The scratch resistance of a sheet or a film layer of an article of the invention typically ranges from about 5 to more than about 500 cycles, preferably greater than about 10 cycles, more preferably greater than 50 cycles and most preferably greater than about 100 cycles.

Taber Abrasion Resistance

A 7.5 cm diameter non-abraded circular sample of the material to be tested is cut such that a 1.25 cm hole is provided in the center of the sample. The haze of the non-abraded sample is then measured using a Gardner XL211 Hazeguard system. The Gardner
15 XL211 Hazeguard system is balanced and calibrated to zero using the non-abraded sample. The sample is clamped in a fixture of a Taber abrader. The sample is abraded using the Taber Abrader with CS10 wheels and a 500 gram load for 100 cycles. The haze of the abraded sample is measured using the Gardner XL211 Hazeguard system. The difference in haze of the abraded surface and the non-abraded surface is recorded.

The Taber abrasion resistance value is the percentage difference between the haze value of the abraded sample and the non-abraded sample. Preferably the Taber abrasion resistance of the sample of the material being tested after 100 cycles is less than about 25 percent, more preferably less than about 10 percent, and most preferably less than about 2 percent.

EXAMPLES

The present invention will be better understood by referring to the following non-limiting examples. All parts, percentages, ratios, etc. in the examples are by weight unless indicated otherwise.

Example 1

A bonding material solution comprising 96 parts by weight of isooctyl acrylate and 4 parts by weight of acrylamide was prepared in a 50% heptane/50% ethyl acetate solution using 2,2'-azobis(isobutyronitrile) free radical initiator available under the trademark "VAZO" 64 from the E.I. DuPont Company, of Wilmington, Delaware.

The following components were added to a reaction vessel: 19.2 kg of isooctyl acrylate, 0.8 kg of acrylamide, 40 kg of heptane and 40 kg of ethyl acetate. While constantly stirring under a nitrogen atmosphere and controlling the temperature between 70–100 ° C, 270 grams of VAZO™ 64 was added to the vessel in three 90-gram increments. The resulting polymer had a conversion of 98%. The Brookfield viscosity was measured (#3 spindle at 12 rpm) at 2000 – 2800 cps at a solids level of 19-23%. The inherent viscosity of the polymer was 1.25-1.40 dl/gram.

A first sheet of film with a tacky bonding layer was prepared by coating the bonding material solution onto a second surface of a 15 cm x 100 cm x 125 micron thick optically clear biaxially oriented corona treated polyester film using a knife coater at a wet thickness of 175 microns. The second surface of the film was the corona treated surface of the film. The coated film was dried in an air convection oven for 10 minutes at 82 ° C. The dry thickness of the coating of the coated film was 20–25 microns. The tacky bonding layer of this first sheet was protected by laminating an optically clear silicone coated polyester film to the tacky bonding layer. The silicone coated polyester film was 1-2 PESTRD (P1)-7200 available from DCP Lohja Inc. of Lohja California. The surface opposite the bonding layer coated surface of the film will be referred to herein as the release surface.

A second sheet of film with a tacky bonding layer was prepared in a similar manner. The bonding layer of the second sheet was laminated to the release surface of the first sheet using a laminator with a steel roll and a rubber backup roll having a shore A hardness of 75 at a pressure of 32 N/cm² such that the bonding layer of the second sheet was in contact with the release surface of the first sheet. This sheet preparation and lamination process was repeated until a stack of four sheets was completed.

Example 2

Example 2 was identical to Example 1 except that the corona treated polyester film was 170 microns in thickness.

5 Example 3

Example 3 was identical to Example 1 except that the corona treated polyester film was 75 microns in thickness.

Example 4

10 Example 4 was identical to Example 1 except that the corona treated polyester film was 250 microns in thickness and the size of the corona treated polyester film was 15 cm x 25 cm.

Example 5

15 Example 5 was identical to Example 1 except that a sufficient number of sheets were made and laminated together until a stack of 10 sheets was prepared.

Example 6

20 Example 6 was identical to Example 1 except that the film onto which the bonding material solution was coated was a 175 micron polyester film with a hard coating on the first surface which served as the release layer. This film and coating was obtained from the Furon Corporation of Worcester, Massachusetts under the product name 007 PET/0270x Hard coat. In addition, the side of the film opposite the release layer was corona treated prior to coating with the bonding material described in Example 1.

25

Example 7

30 A polished 22 cm x 28 cm x 250 micron thick film of clear transparent polycarbonate was obtained from General Electric under the tradename Lexan™ FR60. The film had a first surface and an opposite second surface. The film was coated on its first surface with a solution of 3M 906 hard coat, an acid-resistant acrylic based protective coating available from 3M Company, St Paul, MN in order to provide a release layer and an abrasion resistant surface on one side of the film. The coating solution was made by

diluting to 16 % solids 906 hard coat with a 50/50 mixture of isopropanol and n-butanol. To 100 grams of the diluted hardcoat solution, 0.075 gram of a leveling agent Dow 57, an alkoxy terminated polysilicone available from Dow Corning of Midland, Michigan was added. The coating was applied with a syringe to the first surface of the film in a vertical position approximately 10 microns wet. The sheet was dried 10 minutes at 82 degrees C. The coating on the film was cured with a 300 Watt high pressure mercury vapor lamps at a belt speed of approximately 30 meters per minute. The reflective parabolic lamp housing focused the light source on the coating. The curing unit was Model II 180133 AN from RPC Industries of Plainview, Illinois. The resulting thickness of the hard coat was 1-2 microns.

A bonding material was prepared from 96 parts by weight of isooctyl acrylate and 4 parts by weight of acrylamide in a 50% heptane/50% ethyl acetate solution using VAZO™ 64 initiator as follows.

To a reaction vessel the following materials were added: 19.2 kg of isooctyl acrylate, 0.8 kg of acrylamide, 40 kg of heptane and 40 kg of ethyl acetate. While constantly stirring under a nitrogen atmosphere and controlling the temperature between 70 – 100 ° C, 270 grams of VAZO™ 64 was added to vessel in three 90 gram increments. The resulting polymer solution had a conversion of 98%. The Brookfield viscosity was measured (#3 spindle at 12 rpm) at 2000 – 2800 cps at a solids level of 20%. The inherent viscosity of the polymer solution was 1.40 dl/gram.

The polymer solution was coated on 15 cm x 30 cm x 50 micron thick optically clear biaxially oriented silicone coated optically clear polyester film (transfer film) using a knife coater at a wet thickness of 175 microns. The silicone coated polyester was 1-2 PESTRD (P1)-7200 from DCP Lohja Inc. of Lohja California. The coated film was dried in an air convection oven for 10 minutes at 82 ° C in order to form a transfer tape. The dry thickness of the coated layer was 20-25 microns. The coating was considered to be a bonding layer. The transfer tape was laminated to the non-hard coated surface of the Lexan™ FR60 sheet via the bonding layer of the transfer tape. Any excess Lexan™ FR60 sheet and transfer tape were trimmed so that the trimmed laminate had areas with complete coating of the bonding layer. Four of these trimmed laminates were prepared.

A stack of sheets was produced by removing the optically clear polyester release film from the bonding layer of the first trimmed laminate and laminating it to the release

coated surface of the second trimmed laminate using a laminator with a steel roll and a rubber backup roll with a shore A hardness of 75 at a pressure of 32 N/cm². The optically clear polyester release film was removed from the third trimmed laminate and the third trimmed laminate was laminated to the release coated surface of the first two trimmed laminates. This was repeated until a stack of four trimmed laminates was produced.

Example 8

Example 6 was repeated except the bonding layer was comprised of polyhexene. The film onto which the bonding material layer was coated was a 175 micron thick optically clear polyester with a 0270x hard coat as described in Example 6 from the Furon Corporation of Worcester, Massachusetts.

A bonding material was prepared using a polyhexene with an inherent viscosity of 3.0 dl/gram. The polyhexene was prepared using a process described in U.S. Patent No. 5,644,007 issued on July 1, 1997 and assigned to 3M Company. The polyhexene was prepared using 0.2-0.3 g of a Ziegler-Natta catalyst Lynx™ 715 per kg of monomer. Lynx™ 715 is TiCl₄ supported on MgCl₂ powder which is commercially available from Catalyst Resources Inc. This catalyst is discussed in *Boor, Ziegler-Natta Catalysts and Polymerizations, "Polymerization of Monomers," Ch. 19, pp. 512-562, Academic*. The conversion rate was 15 %. The bonding material was coated on the surface of the film opposite the release layer of the film.

Comparative Example 9

Four layers of Scotch™ 375 packaging tape from 3M Company in St. Paul, MN were laminated together using a laminator with a steel roll and a rubber backup roll with a shore A hardness of 75 at a pressure of 32 N/cm². Each layer of tape was 10 cm x 15 cm and comprised a 50 micron biaxially oriented polypropylene backing and a 37 micron rubber based adhesive coated on one surface thereof. The adhesive on the bottom sheet of the stack was protected by a silicone coated optically clear polyester release liner. The polyester release liner was 1-2 PESTRD(P1)-7200 from DCP Lohja Inc. of Lohja California. The liner was removed from each tape and the tapes were laminated together such that the adhesive layer of one tape was in contact with the film layer of the tape below except for the bottom piece of tape.

Example 1 – 8 and Comparative Example 9 were subjected to various tests. The tests and the results obtained are reported in the table below.

Table

	Example 1	Example 2	Example 3	Example 4	Example 5	Example 6	Example 7	Example 8	Compara- tive Example 9

The foregoing detailed description and Examples have been given for clarity of understanding only. No unnecessary limitations are to be understood therefrom. The invention is not limited to the exact details shown and described, for variations obvious to one skilled in the art will be included within the invention defined by the claims.

5

It is claimed:

1. An article comprising:
a stack of sheets, wherein each sheet independently comprises:
 - 5 (a) a film, the film having a first side having a surface area and an opposite second side having a surface area;
 - (b) a bonding layer having a first side having a surface area and an opposite second side having a surface area, wherein the bonding layer is bonded via its first side to the second side of the film such that at least a center of the surface area of the second side of
10 the film is in contact with the bonding layer, wherein at least about 50 percent of the surface area of the second side of the film has the bonding layer bonded thereto;
 - (c) an optional release layer coated on the first side of the film;
wherein each sheet is stacked upon another sheet such that except for a bottom sheet of the stack of sheets, the bonding layer of a sheet is in contact with the
15 protective film or release layer, if present, of a sheet below;
wherein a topmost sheet can be removed from the stack of sheets by pulling it away from the stack such that the sheet being removed from the stack as well as the sheets remaining with the stack do not delaminate;
wherein the stack of sheets when subjected to a visual acuity test using a 3
20 meter Snellen eye chart can allow an observer with 6 meter/6 meter vision to read a line on the eye chart which is indicative of about 6 meter/ 12 meter vision or better.
2. The article of claim 1 wherein the stack of sheets is transparent.
- 25 3. The article of claim 1 wherein each sheet has a penetration resistance of at least about 0.5 kg.
4. The article of claim 1 which comprises at least about 3 sheets.
- 30 5. The article of claim 1 wherein the film has a thickness ranging from about 25 to about 4000 microns.

6. The article of claim 1 wherein the topmost sheet is capable of being removed by gripping the sheet with an adhesive wand and pulling the sheet away from the stack of sheets of sheets.

5

7. The article of claim 1 wherein the article further comprises a plurality of tabs, wherein a separate tab is bonded to a portion of the second side of the bonding layer of each of the sheets in a manner such that the tab on the topmost sheet can be used to pull the topmost sheet away from the stack of sheets.

10

8. The article of claim 1 wherein each sheet has a hole which extends through that sheet in a margin of the sheet, wherein the holes in the sheets are staggered such that the holes do not overlap and wherein the topmost sheet can be removed from the stack of sheets by using a tool which can be inserted in the hole of the topmost sheet and used to pull the topmost sheet away from the stack.

15

9. A construction comprising:

(i) an article comprising:

20

a stack of sheets, wherein each sheet independently comprises:

(a) a film, the film having a first side having a surface area and an opposite second side having a surface area;

25

(b) a bonding layer having a first side having a surface area and an opposite second side having a surface area, wherein the bonding layer is bonded via its first side to the second side of the film such that at least a center of the surface area of the second side of the film is in contact with the bonding layer, wherein at least about 50 percent of the surface area of the second side of the film has the bonding layer bonded thereto, wherein with respect to each sheet the first side of the film is not bonded to a bonding layer of the same sheet;

30

(c) an optional release layer coated on the first side of the film;

wherein each sheet is stacked upon another sheet such that except for a bottom sheet of the stack of sheets, the bonding layer of a sheet is in contact with the protective film or release layer, if present, of a sheet below;

5 wherein a topmost sheet can be removed from the stack of sheets by pulling it away from the stack such that the sheet being removed from the stack as well as the sheets remaining with the stack do not delaminate;

10 wherein the stack of sheets when subjected to a visual acuity test using a 3 meter Snellen eye chart can allow an observer with 6 meter/6 meter vision to read a line on the eye chart which is indicative of about 6 meter/12 meter vision or better; and

(ii) a substrate to which the article is bonded via the bonding layer of the bottom sheet.

15 10. The construction of claim 16 wherein the substrate is part of a structure.

11. A method comprising the steps of:

(a) applying an article comprising:

a stack of sheets, wherein each sheet independently comprises:

20 (i) a film, the film having a first side having a surface area and an opposite second side having a surface area;

(ii) a bonding layer having a first side having a surface area and an opposite second side having a surface area, wherein the bonding layer is bonded via its first side to the second side of the film such that at least a center of the surface area of the second side of the film is in contact with the bonding layer, wherein at least about 50 percent of the surface area of the second side of the film has the bonding layer bonded thereto, wherein
25 with respect to each sheet the first side of the film is not bonded to a bonding layer of the same sheet;

(iii) an optional release layer coated on the first side of the film;

30 wherein each sheet is stacked upon another sheet such that except for a bottom sheet of the stack of sheets, the bonding layer of a sheet is in contact with the protective film or release layer, if present, of a sheet below;

wherein a topmost sheet can be removed from the stack of sheets by pulling it away from the stack such that the sheet being removed from the stack as well as the sheets remaining with the stack do not delaminate;

5 wherein the stack of sheets when subjected to a visual acuity test using a 3 meter Snellen eye chart can allow an observer with 6 meter/6 meter vision to read a line on the eye chart which is indicative of about 6 meter/12 meter vision or better.

to a substrate via the bonding layer of the bottom sheet of the article;

(b) allowing the topmost sheet of the article to be damaged;

10 (c) removing the damaged topmost sheet of the article by gripping the sheet and pulling it away from the stack, in a manner such that neither the sheet being removed nor the stack of sheets which remains delaminates, in order to expose a lower sheet of the article which thence becomes the topmost sheet of the article.
